Abstract

In this paper we study the time evolution of (Renyi) entanglement entropies for locally excited states in four dimensional free massless fermionic field theory. Locally excited states are defined by being acted by various local operators on the ground state. Their excesses are defined by subtracting (Renyi) entanglement entropy for the ground state from those for locally excited states. They finally approach some constant if the subsystem is given by half of the total space. They have spin dependence. They can be interpreted in terms of quasi-particles.

1 Introduction

Quantum entanglement is an essential idea that distinguishes quantum physics from classical physics. There has been a lot of work done to investigate various subfields of physics from a perspective of quantum entanglement. For instance, the universal properties of quantum entanglement are used to characterize conformal field theories [1, 2, 3, 4], as well as topologically ordered phases [5, 6]. The quantum entanglement also plays an essential role to understand the Hilbert space of gravity [7, 8]. While the most commonly used quantities for characterizing states are correlation functions of operators, quantum entanglement focuses more directly on the Hilbert space.

Entanglement entropy is defined as the von Neumann entropy of a reduced density matrix ρ_A for a subsystem A . It has been observed that the dominant contribution of entanglement entropy in ground states of gapped systems comes from near boundary region of A . This leads to the area law of entanglement entropy [9]. For ground states of gapless systems, the contribution of the entanglement from a long distance does not necessarily become subdominant. Indeed, in 2d conformal field theories (CFTs), entanglement entropy behaves universally as $\frac{c}{3} \log l$ where c is the central charge and l is the size of the subsystem A , suggesting that entanglement of any distance equally contributes to the entropy. Recently some entanglement measures are introduced to describe the more detail structure of the entanglement entropy [10, 11].

The above story is only for static (ground) states and much less is understood for the dynamical aspects of the entanglement entropy as well as the entanglement entropy for excited states. There are interesting questions about the dynamics of quantum entanglement, such as how the quantum entanglement is created and propagates, how they distributes in space time. Those are essential for understanding far-equilibrium states and their thermalization [12], how efficiently quantum dynamics can be simulated in classical computers, and where and how the black hole information goes.

In this paper, we study the time evolution of (Rényi) entanglement entropies by being acted by a fermionic local operator on the ground state. First we explain quantum quenches which are a useful protocol to investigate the dynamical aspects of the entanglement. Suppose a system is prepared for a Hamiltonian $H(\lambda_0)$ which has an experimentally controllable parameter λ_0 . The state prepared for this system is given by a ground state. Then at a certain time the parameter is shifted from λ_0 to λ_1 . The prepared state is no longer a ground state of $H(\lambda_1)$ and the state undergoes a time evolution. This kind of control is indeed possible in experiments such as cold atom systems [13]. When parameters are changed globally, these protocols are called as global quenches [14]. On the other hand, it is called as local quenches if parameters are changed locally [15].

Our protocol is similar to local quenches. In our setup, parameters of Hamiltonian are not changed. Instead of being changed them, a local operator $\mathcal{O}(t_0, x_0)$ acts on the ground state at certain time and creates entangled quasi-particle. In CFTs they propagate spherically at the speed of light. If this local operator is inserted outside of A , a part of quasi-particles eventually enters into the subsystem A and the rest part stays outside. Since they are entangled, it may create an entanglement between the

subsystem A and the rest of the system. Indeed this kind of behavior, the increase of the entanglement and the saturation, has been observed in various quantum field theories [16, 17, 18, 19, 20, 21, 22]. On the other hand, in holographic field theories the excesses of (Rényi) entanglement entropies do not saturate and keep to increase logarithmically even if time passes efficiently [19, 24, 23].

The standard method for computing the entanglement entropy for ground states or thermal states in path integral is the replica method: we compute the (Rényi) entanglement entropy $S_A^{(n)} = \frac{1}{1-n} \log \text{tr}_A \rho_A^n$ first and then take $n \rightarrow 1$ limit, which gives entanglement entropy $S_A = -\text{tr}_A \rho_A \log \rho_A$. Here $\rho_A = \text{tr}_B \rho$ and we trace out the degrees of freedom outside A (the region B).

We consider free massless fermionic field theory in 4 dimensional spacetime and take a half space as the subsystem A . We generate an excitation by being acted by local operator \mathcal{O} at a distance l away from the entangling surface and time $-t$. The state prepared is given by a locally excited state.

$$|\Psi\rangle = \mathcal{N} \mathcal{O}(-t, -l, \mathbf{x}) |0\rangle, \quad (1)$$

where $\mathbf{x} = (x_2, x_3)$. We define the excesses of (Rényi) entanglement entropies $\Delta S_A^{(n)}$ by subtracting (Rényi) entanglement entropies for the ground state from those for locally excited states.

They do not change for $t < l$, as expected from the causality. The main difference is the final values of $\Delta S_A^{(n)}$: In the case of free massless fermionic field case, $\Delta S_A^{(n)}$ have spin dependence. Their density matrices can depend on the direction of spin because the probability with which (anti-)particles are included in A can depend on the direction of spin. In the free massless scalar field theory, of course $\Delta S_A^{(n)}$ do not have such a dependence.

This paper is organized as follows.

In Sec.2, we explain our setup. In Sec.3, we explain the replica method and the analytic continuation which we perform. In Sec.4 we derive the Green function in 4d free massless fermionic field theory on the replica space. In Sec.5 we compute the time evolution of $\Delta S_A^{(n)}$. In Sec.6 we explain the same thing in terms of quasi-particles. In Sec.7, we conclude and discuss our results.

2 Setup

We study the time evolution of excesses of (Rényi) entanglement entropies for locally excited states which are defined by being acted by various local operators on the ground states in following setup. We consider the 4 dimensional free massless fermionic theory,

$$S_{\text{fermion}} = - \int d^4x \bar{\psi} \gamma^\mu \partial_\mu \psi, \quad (2)$$

where $\gamma^\mu = \{\gamma^t, \gamma^1, \gamma^2, \gamma^3\}$ and $\bar{\psi} = i\psi^\dagger \gamma^t$.

Figure. 1: The location of an local operator and the subsystem A in the Minkowski spacetime.

A local operator \mathcal{O} acts on the ground state as in Figure.1. A locally excited state is given by

$$|\Psi\rangle = \mathcal{N}\mathcal{O}(-t, -l, \mathbf{x}) |0\rangle, \quad (3)$$

where $\mathbf{x} = (x^2, x^3)$ and \mathcal{N} is a normalization constant.

The subsystem A is given by a half of the total space, $x^1 \geq 0$ as in Figure.1. We trace out the degrees of freedom in the complement space B outside A and define a reduced density matrix,

$$\rho_A^{EX} = \text{tr}_B \rho^{EX} \quad (4)$$

where $\rho = |\Psi\rangle \langle\Psi|$.

By using this reduced density matrix, (Rényi) entanglement entropy for locally excited state is defined by

$$S_A^{(n)EX} = \frac{1}{1-n} \log [\text{tr}_A (\rho_A^{EX})^n]. \quad (5)$$

By using the reduced density matrix for the ground state $\rho_A^G = \text{tr}_B |0\rangle \langle 0|$, (Rényi) entanglement entropy for the ground state is defined by

$$S_A^{(n)G} = \frac{1}{1-n} \log [\text{tr}_A (\rho_A^G)^n]. \quad (6)$$

We define the excess of (Rényi) entanglement entropy by subtracting $S_A^{(n)G}$ from $S_A^{(n)EX}$,

$$\Delta S_A^{(n)} = S_A^{(n)EX} - S_A^{(n)G}. \quad (7)$$

We will study the time evolution of $\Delta S_A^{(n)}$ in following sections.

3 Replica Trick

3.1 Locally Excited States

In this section, we explain the replica method for locally excited states. The states we are considering are given as follows:

$$|\Psi\rangle = \mathcal{N} e^{-iHt} e^{-\epsilon H} \mathcal{O}(-l, \mathbf{x}) |0\rangle. \quad (8)$$

Here $\mathcal{O}(-l, \mathbf{x})$ is a local operator in Schrödinger picture and we introduce the regularization factor $e^{-\epsilon H}$ because the norm of the state $|\Psi\rangle$ is divergent without $e^{-\epsilon H}$ and $|\Psi\rangle$ does not belong to the Hilbert space. This corresponds to smearing the point like excitation.

The density matrix ρ is given by

$$\begin{aligned} \rho &= \mathcal{N}^2 e^{-iHt} e^{-\epsilon H} \mathcal{O}(-l, \mathbf{x}) |0\rangle \langle 0| \mathcal{O}(-l, \mathbf{x})^\dagger e^{-\epsilon H} e^{iHt} \\ &= \mathcal{N}^2 \mathcal{O}(\tau_e, -l, \mathbf{x}) |0\rangle \langle 0| \mathcal{O}^\dagger(\tau_l, -l, \mathbf{x}) \end{aligned} \quad (9)$$

Here $\mathcal{O}(\tau, -l, \mathbf{x})$ is a local operator in Heisenberg picture and in the second line we introduce complex times $\tau_e = -\epsilon - it$ and $\tau_l = \epsilon - it$. In the calculation of (Rényi) entanglement entropy, we first treat complex times τ_e and τ_l as if they are real parameters and finally we analytically continue to complex values.

3.2 Replica method

Now we explain the replica method for locally excited states. In the path integral formalism, we can express the wave functional for locally excited states is given by

$$\Psi(\phi(x)) = (Z_1^{EX})^{-\frac{1}{2}} \langle \phi | \Psi \rangle = \int_{\phi(\tau=-\infty, x^i)}^{\phi(\tau=0, x^i)=\phi(x^i)} \mathcal{D}\phi \mathcal{O}(\tau_e, -l, \mathbf{x}) e^{-S[\phi]}. \quad (10)$$

In the same manner, the we can express the bra vector as follows:

$$\Psi^*(\phi(x)) = (Z_1^{EX})^{-\frac{1}{2}} \langle \Psi | \phi \rangle = \int_{\phi(\tau=0, x^i)=\phi(x^i)}^{\phi(\tau=\infty, x^i)} \mathcal{D}\phi \mathcal{O}^\dagger(\tau_l, -l, \mathbf{x}) e^{-S[\phi]}. \quad (11)$$

Then, the density matrix for total system is given by the path integral on the space which has boundary at $\tau = +0$ and $\tau = -0$:

$$\begin{aligned} [\rho_{tot}]_{\phi\phi'} &= \langle \phi | \Psi \rangle \langle \Psi | \phi' \rangle \\ &= (Z_1^{EX})^{-1} \int_{\phi(\tau=+0, x^i)=\phi'(x^i), \phi(\tau=-0, x^i)=\phi(x^i)} \mathcal{D}\phi \mathcal{O}^\dagger(\tau_l, -l, \mathbf{x}) \mathcal{O}(\tau_e, -l, \mathbf{x}) e^{-S[\phi]}, \end{aligned} \quad (12)$$

where Z_1^{EX} appears in order to keep $\text{tr}\rho = 1$ and it is given by

$$Z_1^{EX} = \int_{\phi(\tau=-\infty, x^i)}^{\phi(\tau=\infty, x^i)} \mathcal{D}\phi \mathcal{O}^\dagger(\tau_l, -l, \mathbf{x}) \mathcal{O}(\tau_e, -l, \mathbf{x}) e^{-S[\phi]}. \quad (13)$$

Figure. 2: n -sheeted manifold with operator insertion

Partial trace corresponds to sawing the region which was traced out, so the reduced density matrix is given by

$$[\rho_A^{EX}]_{\phi\phi'} = (Z_1^{EX})^{-1} \int_{\phi(\tau=-\infty, x^i)}^{\phi(\tau=\infty, x^i)} \mathcal{D}\phi \mathcal{O}^\dagger(\tau_l, -l, \mathbf{x}) \mathcal{O}(\tau_e, -l, \mathbf{x}) e^{-S[\phi]} \times \prod_{x \in A} \delta(\phi(+0, x^i) - \phi'(x^i)) \cdot \delta(\phi(-0, x^i) - \phi(x^i)). \quad (14)$$

From this we can see that the only difference between the reduced density matrix for ground states and that for locally excited states is the insertion of local operators $\mathcal{O}(\tau_e)$ and $\mathcal{O}(\tau_l)$. We need to insert two local operators in each sheet, so finally we need to insert $2n$ local operators in the n -sheeted manifold Σ_n which is constructed of n flat spaces and it has a conical singularity on the entangling surface as in Figure.2.

Then, the $\text{tr}(\rho_A^{EX})^n$ is given by the partition function with the insertion of $2n$ local operators:

$$\text{tr}(\rho_A^{EX})^n = (Z_1^{EX})^{-n} \int \mathcal{D}\phi \mathcal{O}^\dagger(r_l, \theta_l^n) \mathcal{O}(r_e, \theta_e^n) \cdots \mathcal{O}^\dagger(r_l, \theta_l^1) \mathcal{O}(r_e, \theta_e^1) e^{-S[\phi]}. \quad (15)$$

where we introduce the polar coordinate (r, θ) on (τ, x_1) plane, the region of θ is given by $0 < \theta < 2\pi n$ and $\theta_{e,l}^k = \theta_{e,l}^1 + 2\pi(k-1)$, see Figure.2. (15) is almost the correlation function and the only difference is that right hand side is divided by $(Z_1^{EX})^n$, not by Z_n where Z_n is the partition function on n -sheeted manifold Σ_n without any operator insertion. If we consider the difference between Rényi entanglement entropy for excited states and that for the ground state, we can find that it is expressed by the correlation

function on n -sheeted manifold:

$$\begin{aligned}\Delta S_A^{(n)} &= \frac{1}{1-n} \left(\log \frac{\text{tr}_A(\rho_A^{EX})^n}{(\text{tr}_A \rho_A^{EX})^n} - \log \frac{\text{tr}_A(\rho_A^G)^n}{(\text{tr}_A \rho_A^G)^n} \right) = \frac{1}{1-n} \left(\log \frac{Z_n^{EX}}{Z_n} - n \log \frac{Z_1^{EX}}{Z_1^G} \right) \\ &= \frac{1}{1-n} (\log \langle \mathcal{O}^\dagger(r_l, \theta_l^n) \mathcal{O}(r_e, \theta_e^n) \cdots \mathcal{O}^\dagger(r_l, \theta_l^1) \mathcal{O}(r_e, \theta_e^1) \rangle_{\Sigma_n} - n \log \langle \mathcal{O}(r_e, \theta_e^1) \mathcal{O}^\dagger(r_l, \theta_l^1) \rangle_{\Sigma_1}).\end{aligned}\quad (16)$$

In this way, we can express the difference of (Rényi) entanglement entropy using the correlation function on n -sheeted manifold.

4 Propagator

In conformal field theories, (Rényi) entanglement entropy for a ground state is invariant under the conformal transformation. In order to preserve its conformal symmetry in the replica trick, the action on Σ_n is given by

$$S = \int_{\Sigma_n} dV \bar{\psi} \Gamma^\mu \nabla_\mu \psi, \quad (17)$$

where $\Gamma^i (i = 0, 1, 2, 3)$ obeys the clifford algebra ($\{\Gamma^i, \Gamma^j\} = 2\delta_{i,j} \mathbf{1}$) and $\mathbf{1}$ is the identity.

In this case, Σ_n is given by the flat space except for the origin. We introduce a polar coordinate and this geometry is described by

$$ds^2 = dr^2 + r^2 d\theta^2 + dx_2^2 + dx_3^2. \quad (18)$$

The two point function of ψ and $\bar{\psi}$ is defined by

$$- \langle \mathcal{T} \psi_a(r, \theta, \mathbf{x}) \bar{\psi}_b(r_2, \theta_2, \mathbf{x}_2) \rangle = S_{ab}(r, r_2, \theta, \theta_2, \mathbf{x}, \mathbf{x}_2). \quad (19)$$

S_{ab} obeys the equation of motion as follows,

$$\left(e_i^\mu \Gamma^i \partial_\mu + \frac{\Gamma^0}{2r} \right) S(r, r_2, \theta, \theta_2, \mathbf{x}, \mathbf{x}_2) = -\mathbf{1} \frac{\delta(r - r_2) \delta(\theta - \theta_2) \delta(\mathbf{x} - \mathbf{x}_2)}{r}. \quad (20)$$

S_{ab} can be rewritten by

$$S_{ab} = \left(e_i^\mu \Gamma^i \partial_\mu + \frac{\Gamma^0}{2r} \right) g(r, r_2, \theta, \theta_2, \mathbf{x}, \mathbf{x}_2). \quad (21)$$

g is defined by

$$g(x, x') = \mathbf{1} \text{Re} H(r, r_2, \theta, \theta_2, \mathbf{x}, \mathbf{x}_2) + \Gamma^0 \Gamma^1 \text{Im} H(r, r_2, \theta, \theta_2, \mathbf{x}, \mathbf{x}_2). \quad (22)$$

where $H(x, x')$ is given by

$$H(r, r_2, \theta, \theta_2, \mathbf{x}, \mathbf{x}_2) = \exp \left(i \frac{\theta - \theta'}{2} \right) G(r, r_2, \theta, \theta_2, \mathbf{x}, \mathbf{x}_2). \quad (23)$$

$G(r, r_2)$ obeys the following equation of motion,

$$\left(\frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{1}{r^2} \frac{\partial^2}{\partial \theta^2} + \frac{\partial^2}{(\partial x^2)^2} + \frac{\partial^2}{(\partial x^3)^2} \right) G(r, r_2, \theta, \theta_2, \mathbf{x}, \mathbf{x}_2) = - \frac{\delta(r - r_2) \delta(\theta - \theta_2) \delta(\mathbf{x} - \mathbf{x}_2)}{r}. \quad (24)$$

Next we consider the boundary condition for $\psi(x)$ ¹. It is given by,

$$\psi(r, \theta + 2n\pi, \mathbf{x}) = -\psi(r, \theta, \mathbf{x}). \quad (25)$$

Then the boundary condition for two point function of ψ is given by

$$S_{ab}(r, \theta + 2n\pi, \mathbf{x}) = -S_{ab}(r, \theta, \mathbf{x}). \quad (26)$$

The boundary condition for the green function G is given by

$$G(r, \theta + 2n\pi, \mathbf{x}) = e^{i(-n+1)\pi} G(r, \theta, \mathbf{x}). \quad (27)$$

4.1 Computation of Propagator

Let's compute the propagator $G(r, r', \theta, \theta')$. It can be expanded by the eigenfunctions $V(r, \theta, \mathbf{x})$ which are defined by

$$\mathcal{L}V(r, \theta, \mathbf{x}) = -(k^2 + \mathbf{k}^2)V(r, \theta, \mathbf{x}), \quad (28)$$

where $\mathcal{L} = \left(\frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{1}{r^2} \frac{\partial^2}{\partial \theta^2} + \frac{\partial^2}{(\partial x^2)^2} + \frac{\partial^2}{(\partial x^3)^2} \right)$.

After expanding it, it is given by

$$G(x, x') = \frac{1}{2n\pi} \frac{1}{(2\pi)^2} \sum_{l=-\infty}^{\infty} \int d\mathbf{k} \int_0^{\infty} dk k \frac{J_{|\frac{-n+1+2l}{2n}|}(kr) J_{|\frac{-n+1+2l}{2n}|}(kr')}{k^2 + \mathbf{k}^2} \times e^{i(\frac{-n+1+2l}{2n})(\theta-\theta')} e^{i\mathbf{k}(\mathbf{x}-\mathbf{x}')}, \quad (29)$$

where $J_\nu(x)$ is the Bessel function of the first kind. We can rewrite this green function as in [17, 18, 19, 27, 28, 29]. It is given by

$$G(x, x') = \frac{1}{8\pi^2 n r r'} \sum_{l=-\infty}^{\infty} \frac{e^{-|\frac{-n+1+2l}{2n}|t_0 + i(\frac{-n+1+2l}{2n})(\theta-\theta')}}{\sinh t_0}, \quad (30)$$

where t_0 is defined by

$$\cosh t_0 = \frac{r^2 + r'^2 + |\mathbf{x} - \mathbf{x}'|^2}{2rr'}. \quad (31)$$

¹By using the map in [31], entanglement entropy for the spherical subsystem is map to the thermal entropy in the hyperbolic space. This boundary condition in (25) agrees with the one which is imposed on fermionic field along S^1 direction.

If n is odd, the green function is given by

$$G(x, x') = \frac{1}{8\pi^2 n r r'} \frac{\sinh \frac{t_0}{n}}{\sinh t_0 \left(\cosh \left(\frac{t_0}{n} \right) - \cos \left(\frac{\theta - \theta'}{n} \right) \right)} \quad (32)$$

In this case, the boundary condition (27) is given by

$$G(r, \theta + 2n\pi, \mathbf{x}) = G(r, \theta, \mathbf{x}). \quad (33)$$

The green function given by (32) obeys this boundary condition.

If n is even, the green function is

$$G(x, x') = \frac{1}{4\pi^2 n r r'} \frac{\cos \left(\frac{\theta - \theta'}{2n} \right) \sinh \frac{t_0}{2n}}{\sinh t_0 \left(\cosh \left(\frac{t_0}{n} \right) - \cos \left(\frac{\theta - \theta'}{n} \right) \right)}. \quad (34)$$

In this case, boundary condition given by (27) is given by

$$G(r, \theta + 2n\pi, \mathbf{x}) = -G(r, \theta, \mathbf{x}). \quad (35)$$

4.2 Analytic Continuation to Real Time

Up to here, we consider propagators in the Euclidean space. Two local operators are located as in Figure.3. We would like to study the time evolution of (Rényi) entanglement entropy. Therefore we perform an analytic continuation to real time as follows,

$$\begin{aligned} \tau_l &= \epsilon - it, \\ \tau_e &= -\epsilon - it, \end{aligned} \quad (36)$$

where in lorentzian spacetime ϵ is a cutoff parameter which regulates the divergence when a local operator contacts with another.

After performing it, parameters in Euclidean space are related to those in lorentzian spacetime as follows,

$$\begin{aligned} r^2 &= l^2 - t^2 + \epsilon^2 - 2i\epsilon t, \\ r_2^2 &= l^2 - t^2 + \epsilon^2 + 2i\epsilon t, \\ \cos(\theta - \theta_2) &= \frac{l^2 - \epsilon^2 - t^2}{V^2}, \\ \sin(\theta - \theta_2) &= -\frac{2\epsilon t}{V^2}, \\ V^2 &= \sqrt{(l^2 - t^2 + \epsilon^2)^2 + 4\epsilon^2 t^2}. \end{aligned} \quad (37)$$

Figure. 3: The location of operators in Euclidean space.

4.3 Dominant Propagators

After performing the analytic continuation in (36), we take the limit $\epsilon \rightarrow 0$. A few propagators dominantly contribute to n point functions. We call them dominant propagators. They are $\mathcal{O}(\epsilon^{-3})$. If $t \leq l$, dominant propagators on Σ_1 are given by

$$\begin{aligned} S_{ab}(r, r_2, \theta - \theta_2) &= \frac{1}{16\pi^2 \sqrt{l^2 - t^2} \epsilon^3} [it\Gamma_{ab}^0 + l\Gamma_{ab}^1], \\ S_{ab}(r, r_2, \theta_2 - \theta) &= \frac{-1}{16\pi^2 \sqrt{l^2 - t^2} \epsilon^3} [it\Gamma_{ab}^0 + l\Gamma_{ab}^1]. \end{aligned} \quad (38)$$

On the other hand, If $t > l$, they are given by

$$\begin{aligned} S_{ab}(r, r_2, \theta - \theta_2) &= \frac{1}{16\pi^2 \sqrt{t^2 - l^2} \epsilon^3} [il\Gamma_{ab}^0 + t\Gamma_{ab}^1], \\ S_{ab}(r, r_2, \theta_2 - \theta) &= \frac{-1}{16\pi^2 \sqrt{t^2 - l^2} \epsilon^3} [il\Gamma_{ab}^0 + t\Gamma_{ab}^1], \end{aligned} \quad (39)$$

If $t \leq l$, dominant propagators on $\Sigma_{n>1}$ are red arrows in Figure.4. They are given by

$$\begin{aligned} S_{ab}(r, r_2, \theta - \theta_2) &= \frac{1}{16\pi^2 \sqrt{l^2 - t^2} \epsilon^3} [it\Gamma_{ab}^0 + l\Gamma_{ab}^1], \\ S_{ab}(r_2, r, \theta_2 - \theta) &= \frac{-1}{16\pi^2 \sqrt{l^2 - t^2} \epsilon^3} [it\Gamma_{ab}^0 + l\Gamma_{ab}^1]. \end{aligned} \quad (40)$$

If $t > l$, they are red arrows and blue arrows in Figure.4. They are given by

$$\begin{aligned}
S_{ab}(r, r_2, \theta - \theta_2) &= \frac{(t+l)^2}{64\pi^2 t \sqrt{t^2 - l^2} \epsilon^3} \left[i\Gamma_{ab}^0 + \frac{2t-l}{t} \Gamma_{ab}^1 \right], \\
S_{ab}(r_2, r, \theta_2 - \theta) &= \frac{-(t+l)^2}{64\pi^2 t \sqrt{t^2 - l^2} \epsilon^3} \left[i\Gamma_{ab}^0 + \frac{2t-l}{t} \Gamma_{ab}^1 \right], \\
S_{ab}(r, r_2, \theta - \theta_2 + 2\pi) &= \frac{(t-l)^2}{64\pi^2 t \sqrt{t^2 - l^2} \epsilon^3} \left[i\Gamma_{ab}^0 - \frac{2t+l}{t} \Gamma_{ab}^1 \right], \\
S_{ab}(r_2, r, \theta_2 - \theta - 2\pi) &= \frac{-(t-l)^2}{64\pi^2 t \sqrt{t^2 - l^2} \epsilon^3} \left[i\Gamma_{ab}^0 - \frac{2t+l}{t} \Gamma_{ab}^1 \right], \\
S_{ab}(r, r_2, \theta - \theta_2 - 2(n-1)\pi) &= \frac{-(t-l)^2}{64\pi^2 t \sqrt{t^2 - l^2} \epsilon^3} \left[i\Gamma_{ab}^0 - \frac{2t+l}{t} \Gamma_{ab}^1 \right], \\
S_{ab}(r_2, r, \theta_2 - \theta + 2(n-1)\pi) &= \frac{(t-l)^2}{64\pi^2 t \sqrt{t^2 - l^2} \epsilon^3} \left[i\Gamma_{ab}^0 - \frac{2t+l}{t} \Gamma_{ab}^1 \right].
\end{aligned} \tag{41}$$

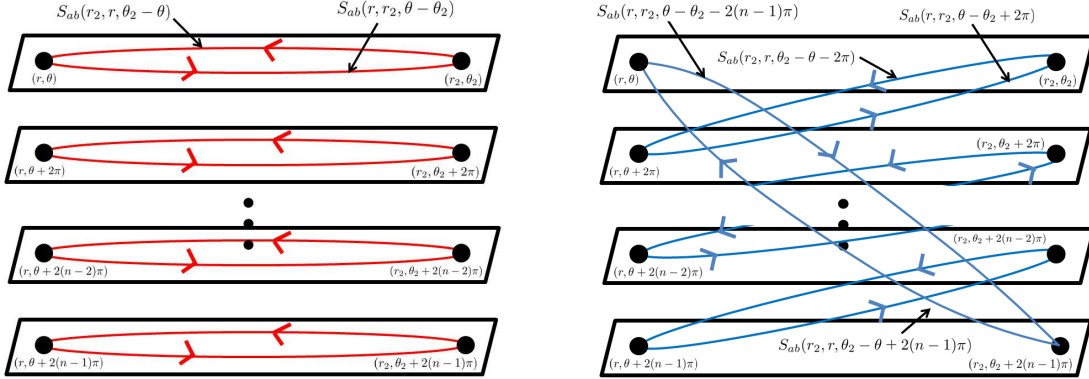

Figure. 4: The schematic description of dominant propagators. $S_{ab}(r, r_2, \theta - \theta_2)$ and $S_{ab}(r_2, r, \theta_2 - \theta)$ correspond to the right arrow and the left arrow respectively.

4.3.1 Propagators in the Cartesian Coordinate

Given locally excited states are defined by being acted by local operators on the ground state in Cartesian coordinate. Therefore we explain the relation between propagators in (17) and them in the Cartesian coordinate. In the Cartesian coordinate, the action in free massless fermionic theory is given by

$$S = \int d^4x \bar{\psi}' \gamma^\mu \partial_\mu \psi', \tag{42}$$

where $\gamma^\mu = \{\gamma^0, \gamma^1, \gamma^2, \gamma^3\}$.

When we introduce a polar coordinate $x^1 = r \cos \theta, x^0 = r \sin \theta$ and redefine the fermionic field by $\psi'(r, \theta) = e^{-\frac{\gamma^1 \gamma^0}{2} \theta} \psi(r, \theta)$, it is rewritten by

$$S = \int dr \int d\theta r \int d^2 \mathbf{x} \bar{\psi} \left[\Gamma^0 \partial_r + \Gamma^1 \frac{\partial_\theta}{r} + \frac{\Gamma^0}{2r} + \Gamma^\mathbf{x} \partial_\mathbf{x} \right] \psi, \quad (43)$$

where $\Gamma^0 = \gamma^1, \Gamma^1 = \gamma^0, \Gamma^\mathbf{x} = \gamma^\mathbf{x}$.

$$\psi'(r, \theta) = \cos\left(\frac{\theta}{2}\right) \psi(r, \theta) + \sin\left(\frac{\theta}{2}\right) \gamma^0 \gamma^1 \psi(r, \theta). \quad (44)$$

After performing this map, the boundary condition for ψ'^2 is mapped to

$$\psi'(r, \theta + 2n\pi) = (-1)^{n+1} \psi'(r, \theta). \quad (45)$$

We define propagators by

$$\begin{aligned} -\langle \mathcal{T} \psi'_a(r, \theta) \bar{\psi}'_b(r_2, \theta_2) \rangle &= S'_{ab}(r, r_2, \theta - \theta_2), \\ -\langle \mathcal{T} \psi'_a(r, \theta) \psi'^{\dagger}_b(r_2, \theta_2) \rangle &= S'_{ac}(r, r_2, \theta - \theta_2) \gamma^0_{cb} = V_{ab}(r, r_2, \theta - \theta_2). \end{aligned} \quad (46)$$

After performing this map, we also perform the analytic continuation in (36) and take the limit $\epsilon \rightarrow 0$. After that, only a few propagators can contribute to n point function dominantly. They are $\mathcal{O}(\epsilon^{-3})$. In any time, dominant propagators on Σ_1 are given by

$$\begin{aligned} S'_{ab}(r, r_2, \theta - \theta_2) &= \frac{-i}{16\pi^2 \epsilon^3} \gamma^t_{ab}, \\ S'_{ab}(r_2, r, \theta_2 - \theta) &= \frac{i}{16\pi^2 \epsilon^3} \gamma^t_{ab}, \\ V_{ab}(r, r_2, \theta - \theta_2) &= \frac{-1}{16\pi^2 \epsilon^3} \mathbf{1}_{ab}, \\ V_{ab}(r_2, r, \theta_2 - \theta) &= \frac{1}{16\pi^2 \epsilon^3} \mathbf{1}_{ab}, \end{aligned} \quad (47)$$

where $\mathbf{1}$ is identity. γ^0 is changed to $i\gamma^t$ ($(\gamma^t)^2 = -\mathbf{1}$).

On the other hand, if $t \leq l$ those on $\Sigma_{n>1}$ are the same as in (47). In the region $t > l$,

²When $n = 1$, ψ' is regular at the origin.

they are given by

$$\begin{aligned}
S'_{ab}(r, r_2, \theta - \theta_2) &= \frac{-i(t+l)}{64\pi^2 t \epsilon^3} \left[\frac{t-l}{t} \gamma_{ab}^1 + 2\gamma_{ab}^t \right], \\
S'_{ab}(r_2, r, \theta_2 - \theta) &= \frac{i(t+l)}{64\pi^2 t \epsilon^3} \left[\frac{t-l}{t} \gamma_{ab}^1 + 2\gamma_{ab}^t \right], \\
S'_{ab}(r, r_2, \theta - \theta_2 + 2\pi) &= \frac{i(t-l)}{64\pi^2 t \epsilon^3} \left[\frac{t+l}{t} \gamma_{ab}^1 - 2\gamma_{ab}^t \right], \\
S'_{ab}(r_2, r, \theta_2 - \theta - 2\pi) &= -\frac{i(t-l)}{64\pi^2 t \epsilon^3} \left[\frac{t+l}{t} \gamma_{ab}^1 - 2\gamma_{ab}^t \right], \\
S'_{ab}(r, r_2, \theta - \theta_2 - 2(n-1)\pi) &= (-1)^{n-1} \frac{i(t-l)}{64\pi^2 t \epsilon^3} \left[\frac{t+l}{t} \gamma_{ab}^1 - 2\gamma_{ab}^t \right], \\
S'_{ab}(r_2, r, \theta_2 - \theta + 2(n-1)\pi) &= (-1)^n \frac{i(t-l)}{64\pi^2 t \epsilon^3} \left[\frac{t+l}{t} \gamma_{ab}^1 - 2\gamma_{ab}^t \right],
\end{aligned} \tag{48}$$

and

$$\begin{aligned}
V_{ab}(r, r_2, \theta - \theta_2) &= -\frac{(t+l)}{64\pi^2 t \epsilon^3} \left[-\frac{t-l}{t} (\gamma^1 \gamma^t)_{ab} + 2\mathbf{1}_{ab} \right], \\
V_{ab}(r_2, r, \theta_2 - \theta) &= \frac{(t+l)}{64\pi^2 t \epsilon^3} \left[-\frac{t-l}{t} (\gamma^1 \gamma^t)_{ab} + 2\mathbf{1}_{ab} \right], \\
V_{ab}(r, r_2, \theta - \theta_2 + 2\pi) &= \frac{(t-l)}{64\pi^2 t \epsilon^3} \left[-\frac{t+l}{t} (\gamma^1 \gamma^t)_{ab} - 2\mathbf{1}_{ab} \right], \\
V_{ab}(r_2, r, \theta_2 - \theta - 2\pi) &= -\frac{(t-l)}{64\pi^2 t \epsilon^3} \left[-\frac{t+l}{t} (\gamma^1 \gamma^t)_{ab} - 2\mathbf{1}_{ab} \right], \\
V_{ab}(r, r_2, \theta - \theta_2 - 2(n-1)\pi) &= (-1)^{n-1} \frac{(t-l)}{64\pi^2 t \epsilon^3} \left[-\frac{t+l}{t} (\gamma^1 \gamma^t)_{ab} - 2\mathbf{1}_{ab} \right], \\
V_{ab}(r_2, r, \theta_2 - \theta + 2(n-1)\pi) &= (-1)^n \frac{(t-l)}{64\pi^2 t \epsilon^3} \left[-\frac{t+l}{t} (\gamma^1 \gamma^t)_{ab} - 2\mathbf{1}_{ab} \right].
\end{aligned} \tag{49}$$

Let's study the time evolution of $\Delta S_A^{(n)}$ in the next section.

5 $\Delta S_A^{(n)}$ for Various Local Operators

In this section, we study the time evolution of $\Delta S_A^{(n)}$ for various operators by the replica trick. Especially, we focus on their behavior in the late time region ($t \gg l$).

5.1 $\Delta S_A^{(n)}$ for ψ'_a

The locally excited state is given by

$$|\Psi\rangle = \mathcal{N} \psi'_a(-t, -l, \mathbf{x}) |0\rangle. \tag{50}$$

The time evolution of $\Delta S_A^{(n)}$ is as follows.

5.1.1 The Excess of Rényi Entanglement Entropies

$\Delta S_A^{(n)}$ for it is given by

$$\Delta S_A^{(n)} = \frac{1}{1-n} \log \left[\frac{\langle \psi_a'^{\dagger}(\theta + 2(n-1)\pi) \psi_a'(\theta_2 + 2(n-1)\pi) \cdots \psi_a'^{\dagger}(\theta) \psi_a'(\theta_2) \rangle_{\Sigma_n}}{\langle \psi_a'^{\dagger}(\theta) \psi_a'(\theta_2) \rangle_{\Sigma_1}^n} \right]. \quad (51)$$

When we take the limit $\epsilon \rightarrow 0$, $\Delta S_A^{(n)}$ vanishes in the early time region ($t \leq l$). When t is greater than l , two diagram in Figure.5 dominantly contribute to $\Delta S_A^{(n)}$. In this region the denominator is given by

$$\langle \psi_a(r, \theta)^{\dagger} \psi_a(r_2, \theta_2) \rangle_{\Sigma_1}^n \sim \left(\frac{1}{16\pi^2 \epsilon^3} \right)^n. \quad (52)$$

Therefore $\Delta S_A^{(n)}$ is given by

$$\begin{aligned} \Delta S_A^{(n)} &= \frac{1}{1-n} \log [A_1 + A_2], \\ A_1 &= \left(\frac{t+l}{4t} \right)^n \left(\left(\frac{t-l}{t} \right) (\gamma^t \gamma^1)_{aa} + 2 \right)^n, \\ A_2 &= \left(\frac{t-l}{4t} \right)^n \left(- \left(\frac{t+l}{t} \right) (\gamma^t \gamma^1)_{aa} + 2 \right)^n, \end{aligned} \quad (53)$$

where $(\gamma^t \gamma^1)_{aa}$ is real because $\gamma^t \gamma^1$ is a hermitian matrix³. If we take the late time limit ($t \gg l$), $\Delta S_A^{(n)}$ is given by

$$\begin{aligned} \Delta S_A^{(n)} &= \frac{1}{1-n} \log [A_1 + A_2], \\ A_1 &= \left(\frac{(\gamma^t \gamma^1)_{aa} + 2}{4} \right)^n, \\ A_2 &= \left(\frac{-(\gamma^t \gamma^1)_{aa} + 2}{4} \right)^n, \end{aligned} \quad (54)$$

where as in Figure.5, A_1 and A_2 are respectively given by

$$\begin{aligned} A_1 &= \frac{(V_{aa}(r_2, r, \theta_2 - \theta))^n}{\langle \psi_a'^{\dagger}(r, \theta) \psi_a'(r_2, \theta_2) \rangle_{\Sigma_1}^n}, \\ A_2 &= \frac{(-1)^{n+1} (V_{aa}(r_2, r, \theta_2 - \theta - 2\pi))^{n-1} V_{aa}(r_2, r, \theta_2 - \theta + 2(n-1)\pi)}{\langle \psi_a'^{\dagger}(r, \theta) \psi_a'(r_2, \theta_2) \rangle_{\Sigma_1}^n}. \end{aligned} \quad (55)$$

³ $-1 \leq (\gamma^t \gamma^1)_{aa} \leq 1$.

If we take the Von Neumann limit $n \rightarrow 1$, ΔS_A is given by

$$\Delta S_A = \frac{1}{4}((\gamma^t \gamma^1)_{aa} - 2) \log(2 - (\gamma^t \gamma^1)_{aa}) - \frac{1}{4}((\gamma^t \gamma^1)_{aa} + 2) \log((\gamma^t \gamma^1)_{aa} + 2) + \log(4). \quad (56)$$

If $(\gamma^t \gamma^1)_{aa}$ vanishes, ΔS_A is given by $\log 2$ which is entanglement entropy for the EPR state. The lower value of ΔS_A in (56) is given by $\log 4/3^{\frac{3}{4}}$ ($(\gamma^t \gamma^1)_{aa} = 1$ or -1).

5.1.2 Reduced Density Matrix

If we identify A_1 and A_2 as the diagonal components of ρ_A^n respectively, it is expected that the density matrix for this state is given by

$$\rho_A = \frac{1}{4} \begin{pmatrix} (\gamma^t \gamma^1)_{aa} + 2 & 0 \\ 0 & -(\gamma^t \gamma^1)_{aa} + 2 \end{pmatrix}, \quad (57)$$

where $\text{tr}_A \rho_A$ and each diagonal components of ρ_A are positive.

It is expected that the density matrix for $|\Psi\rangle = \mathcal{N} \bar{\psi}'_a |0\rangle$ is given by

$$\rho_A = \frac{1}{4} \begin{pmatrix} (\gamma^1 \gamma^t)_{aa} + 2 & 0 \\ 0 & -(\gamma^1 \gamma^t)_{aa} + 2 \end{pmatrix}. \quad (58)$$

Figure. 5: The schematic description of A_1 and A_2 .

5.2 $\Delta S_A^{(n)}$ for $\bar{\psi}' \psi'$

A locally excited state is given by

$$|\Psi\rangle = \mathcal{N} \bar{\psi}' \psi'(-t, -l, \mathbf{x}) |0\rangle, \quad (59)$$

which is invariant for $SL(2, \mathbf{C})$ transformation.

Let's study the time evolution of $\Delta S_A^{(n)}$.

5.2.1 The Excess of (Rényi) Entanglement Entropy

$\Delta S_A^{(2)}$ for (59) is given by

$$\Delta S_A^{(2)} = -\log \left[\frac{\langle \bar{\psi}\psi(\theta + 2\pi)\bar{\psi}\psi(\theta_2 + 2\pi)\bar{\psi}\psi(\theta)\bar{\psi}\psi(\theta_2) \rangle_{\Sigma_2}}{\langle \bar{\psi}\psi(\theta)\bar{\psi}\psi(\theta_2) \rangle_{\Sigma_1}^2} \right] \quad (60)$$

In the early time region ($t \leq l$), $\Delta S_A^{(2)}$ vanishes when we take the limit $\epsilon \rightarrow 0$. On the other hand, in the region $t > l$, $\Delta S_A^{(2)}$ is given by

$$\begin{aligned} \Delta S_A^{(2)} &= -\log [A_1 + A_2 + A_3], \\ A_1 &= \left[\frac{c(t+l)^4}{2^4 c t^2 (t^2 - l^2)} \left[\left(\frac{2t-l}{t} \right)^2 - 1 \right] \right]^2, \\ A_2 &= \left[\frac{c(t-l)^4}{2^4 c t^2 (t^2 - l^2)} \left[\left(\frac{2t+l}{t} \right)^2 - 1 \right] \right]^2, \\ A_3 &= 2c \left[\left(\frac{t^2 - l^2}{2^4 t^2 c} \right)^2 \left[\left(\frac{5t^2 - l^2}{t^2} \right)^2 + 16 \right] \right], \end{aligned} \quad (61)$$

where $c = 4$.

If we take the limit $t \rightarrow \infty$, $\Delta S_A^{(2)}$ is given by

$$\Delta S_A^{(2)} = \log \left[\frac{2^9}{77} \right] \quad (62)$$

If $t \leq l$, for arbitrary n , $\Delta S_A^{(n)}$ vanishes. In the region $t > l$, $\Delta S_A^{(n)}$ is given by

$$\Delta S_A^{(n)} = \frac{1}{1-n} \log [A_1 + A_2 + A_3], \quad (63)$$

where A_1, A_2, A_3 are given by

$$\begin{aligned} A_1 &= \left[\frac{c(t+l)^4}{2^4 c t^2 (t^2 - l^2)} \left[\left(\frac{2t-l}{t} \right)^2 - 1 \right] \right]^n \\ A_2 &= \left[\frac{c(t-l)^4}{2^4 c t^2 (t^2 + l^2)} \left[\left(\frac{2t+l}{t} \right)^2 - 1 \right] \right]^n \\ A_3 &= 2c \left(\frac{t^2 - l^2}{2^4 t^2 c} \right)^n \left[\sum_{k \in 2\mathbb{Z}}^{k \leq n} {}_n C_k 4^k \left(\frac{5t^2 - l^2}{t^2} \right)^{n-k} \right]. \end{aligned} \quad (64)$$

If we take the late time limit $t \rightarrow \infty$, $\Delta S_A^{(n)}$ is given by

$$\Delta S_A^{(n)} = \frac{1}{1-n} \log \left[2 \left(\frac{12}{64} \right)^n + 8 \left(\frac{1}{64} \right)^n \sum_{k \in 2\mathbb{Z}}^{k \leq n} {}_n C_k 4^k 5^{n-k} \right]. \quad (65)$$

5.2.2 Reduced Density Matrix

By using results up to here, we are able to guess the reduce density matrix for $|\Psi\rangle = \mathcal{N}\bar{\psi}'\psi'$ as follows. In the limit $\epsilon \rightarrow 0$, only four diagrams in Figure.6 can contribute to $\Delta S_A^{(n)}$. We define A_1, A_2, A by

$$\begin{aligned} A_1 &= \frac{12}{64}, \\ A_2 &= \frac{12}{64}, \\ A &= \frac{1}{64} \begin{pmatrix} 5 & 4 \\ 4 & 5 \end{pmatrix}. \end{aligned} \tag{66}$$

In the replica trick, $(A_1)^n$, $(A_2)^n$ and $8 \cdot \text{tr}(A^n)$ respectively correspond to the red-lined diagram, blue lined diagram and green lined diagrams in Figure.6. Therefore it is expected that the reduced density matrix for this state is given by the 10×10 matrix,

$$\rho_A = \frac{1}{64} \begin{pmatrix} 12 & 0 & 0 & 0 & 0 & 0 \\ 0 & \tilde{A} & 0 & 0 & 0 & 0 \\ 0 & 0 & \tilde{A} & 0 & 0 & 0 \\ 0 & 0 & 0 & \tilde{A} & 0 & 0 \\ 0 & 0 & 0 & 0 & \tilde{A} & 0 \\ 0 & 0 & 0 & 0 & 0 & 12 \end{pmatrix}, \tag{67}$$

where \tilde{A} is given by the 2×2 matrix,

$$\tilde{A} = \begin{pmatrix} 5 & 4 \\ 4 & 5 \end{pmatrix}. \tag{68}$$

If we diagonalize the matrix \tilde{A} , it is given by

$$\tilde{A} = \begin{pmatrix} 9 & 0 \\ 0 & 1 \end{pmatrix}. \tag{69}$$

For any n , (Rényi) entanglement entropy is given by

$$\Delta S_A^{(n)} = \frac{1}{1-n} \log \left[\frac{2 \cdot 12^n + 4 \cdot 9^n + 4}{2^{6n}} \right] \tag{70}$$

If we take the von Neumann entropy limit $n \rightarrow 1$, entanglement entropy is given by

$$\Delta S_A = \frac{3}{4} \log \left(\frac{128}{9} \right). \tag{71}$$

Min entropy is given by

$$\Delta S_A^{(\infty)} = \log \left(\frac{16}{3} \right). \tag{72}$$

(Rényi) entanglement entropy for this state monotonically decreases when the replica number n increases. Therefore we can consider $\Delta S_A^{(\infty)}$ as the lower bound of (Rényi) entanglement entropies.

If we take the large N limit in the $U(N)$ or $SU(N)$ free massless fermionic field theory, the number of diagrams which can dominantly contribute to $\Delta S_A^{(n)}$ decreases. Because the number of trace in the green-lined diagram is less than that in the others, the blue-lined and red-lined diagram dominantly contribute to $\Delta S_A^{(n)}$ in the large N limit. Therefore it is given by

$$\Delta S_A^{(n \geq 2)} = \frac{2n-1}{n-1} \log 2 + \frac{n}{1-n} \log \left(\frac{3}{4} \right). \quad (73)$$

After that, if we take $n \rightarrow \infty$ limit, Min entropy is given by

$$\Delta S_A^{(\infty)} = \log \left(\frac{16}{3} \right). \quad (74)$$

This result describes that Min entropy is same as (72) even if we take the large N limit.

Figure. 6: The schematic explanation of the correspondence between diagrams and components of a reduce density matrix.

5.3 $\Delta S_A^{(n)}$ for $\psi'^{\dagger} \psi'$

A locally excited state is given by

$$|\Psi\rangle = \mathcal{N} \psi'^{\dagger} \psi'(-t, -l, \mathbf{x}) |0\rangle, \quad (75)$$

which is variant under the $SL(2, \mathbf{C})$ transformation.

5.3.1 The Excess of (Rényi) Entanglement Entropy

$\Delta S_A^{(2)}$ for the state in (75) is given by

$$\Delta S_A^{(2)} = -\log \left[\frac{\langle \psi'^{\dagger} \psi'(\theta + 2\pi) \psi'^{\dagger} \psi'(\theta_2 + 2\pi) \psi'^{\dagger} \psi'(\theta) \psi'^{\dagger} \psi'(\theta_2) \rangle_{\Sigma_2}}{\langle \psi'^{\dagger} \psi'(\theta) \psi'^{\dagger} \psi'(\theta_2) \rangle_{\Sigma_1}^2} \right]. \quad (76)$$

If we take the limit $\epsilon \rightarrow 0$, $\Delta S_A^{(2)}$ vanishes in the early time region ($t \leq l$). In the region $t > l$, $\Delta S_A^{(2)}$ nontrivially grows as follows,

$$\begin{aligned}
\Delta S_A^{(2)} &= -\log [A_1 + A_2 + A_3 + A_4], \\
A_1 &= \frac{(t+l)^4}{4^6 t^4} \left(16 + 4 \left(\frac{t-l}{t} \right)^2 \right)^2, \\
A_2 &= \frac{(t-l)^4}{4^6 t^4} \left(16 + 4 \left(\frac{t+l}{t} \right)^2 \right)^2, \\
A_3 &= \frac{(t^2 - l^2)^2}{4^6 t^4} \left(4 \left(\frac{t^2 - l^2}{t^2} - 4 \right)^2 + 4 \times \frac{4l^2}{t^2} \right), \\
A_4 &= \frac{(t^2 - l^2)^2}{4^6 t^4} \left(4 \left(\frac{t^2 - l^2}{t^2} - 4 \right)^2 + 4 \times \frac{4l^2}{t^2} \right).
\end{aligned} \tag{77}$$

If we take the late time limit ($t \gg l$), $\Delta S_A^{(2)}$ is given by

$$\Delta S_A^{(2)} = -\log \left[\frac{20^2}{4^6} + \frac{20^2}{4^6} + \frac{4 \cdot 3^2}{4^6} + \frac{4 \cdot 3^2}{4^6} \right]. \tag{78}$$

If $t \leq l$, for arbitrary n , $\Delta S_A^{(n)}$ vanishes. In the region $t > l$, $\Delta S_A^{(n)}$ is given by

$$\Delta S_A^{(n)} = \frac{1}{1-n} \log [A_1 + A_2 + A_3], \tag{79}$$

where A_1, A_2, A_3 are given by

$$\begin{aligned}
A_1 &= \left[\frac{c(t+l)^2}{2^4 c t^2} \left[\left(\frac{t-l}{t} \right)^2 + 4 \right] \right]^n \\
A_2 &= \left[\frac{c(t-l)^2}{2^4 c t^2} \left[\left(\frac{t+l}{t} \right)^2 + 4 \right] \right]^n \\
A_3 &= 2c \left(\frac{t^2 - l^2}{2^4 t^2 c} \right)^n \left[\sum_{k \in 2\mathbb{Z}}^{k \leq n} {}_n C_k \left(\frac{4l}{t} \right)^k \left(\frac{3t^2 + l^2}{t^2} \right)^{n-k} \right].
\end{aligned} \tag{80}$$

If we take the late time limit $t \rightarrow \infty$, $\Delta S_A^{(n)}$ is given by

$$\Delta S_A^{(n)} = \frac{1}{1-n} \log \left[2 \left(\frac{20}{64} \right)^n + 8 \left(\frac{3}{64} \right)^n \right]. \tag{81}$$

5.4 Reduced Density Matrix

We define B_1, B_2, B by

$$\begin{aligned} B_1 &= \frac{20}{64}, \\ B_2 &= \frac{20}{64}, \\ B &= \frac{1}{64} \begin{pmatrix} 3 & 0 \\ 0 & 3 \end{pmatrix}. \end{aligned} \tag{82}$$

In the replica trick, $(B_1)^n$, $(B_2)^n$ and $8 \cdot \text{tr}(B^n)$ respectively correspond to the red dashed lined diagram, blue dashed lined diagram and green dashed lined diagrams in Figure.7. Therefore it is expected that the reduced density matrix for this state is given by the 10×10 matrix,

$$\rho_A = \frac{1}{2^6} \begin{pmatrix} 20 & 0 & 0 & 0 & 0 & 0 \\ 0 & \tilde{B} & 0 & 0 & 0 & 0 \\ 0 & 0 & \tilde{B} & 0 & 0 & 0 \\ 0 & 0 & 0 & \tilde{B} & 0 & 0 \\ 0 & 0 & 0 & 0 & \tilde{B} & 0 \\ 0 & 0 & 0 & 0 & 0 & 20 \end{pmatrix}, \tag{83}$$

where \tilde{B} is given by 2×2 matrix,

$$\tilde{B} = \begin{pmatrix} 3 & 0 \\ 0 & 3 \end{pmatrix}. \tag{84}$$

If we take Von Neumann entropy limit $n \rightarrow 1$ in (81) entanglement entropy is given by

$$\Delta S_A = \log 16 + \frac{3}{4} \log 2 - \frac{3}{8} \log 3 - \frac{5}{8} \log 5. \tag{85}$$

Although the local operator $\psi'^{\dagger} \psi'$ is not invariant under $SL(2, \mathbf{C})$ transformation, $\Delta S_A^{(n)}$ is invariant under this transformation.

If we take the limit $n \rightarrow \infty$, it is given by

$$\Delta S_A^{(\infty)} = \log \left(\frac{16}{5} \right) \tag{86}$$

If we take the large N limit in the $U(N)$ or $SU(N)$ free massless fermionic field theory, the number of diagrams which can contribute to $\Delta S_A^{(n)}$ decreases. Because the number of trace in green dashed lined diagram is less than that in the others, blue dashed lined and red dashed lined diagram dominantly contribute to $\Delta S_A^{(n)}$ in the large N limit. Therefore it is given by

$$\Delta S_A^{(n)} = \frac{1}{1-n} \log 2 + \frac{n}{1-n} \log \left(\frac{5}{16} \right). \tag{87}$$

If we take $n \rightarrow \infty$ limit, $\Delta S_A^{(\infty)}$ is given by

$$\Delta S_A^{(\infty)} = \log \left(\frac{16}{5} \right). \quad (88)$$

Even if we take the large N limit, the lower bound of $\Delta S_A^{(n)}$ agrees with that in (86) similarly to the result in the previous subsection.

Figure. 7: The schematic explanation of the correspondence between diagrams and components of a reduced density matrix.

5.5 Spin dependence

Here we discuss the spin dependence of the reduced density matrices in (57) and (58). Their components have $(\gamma^t \gamma^1)_{aa}$. Therefore they depend on the direction of the spin. These spin dependences can be understood as follows. To explain why matrix components depend on the spin, we diagonalize $\gamma^t \gamma^1$ and it is given by

$$\gamma^t \gamma^1 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}. \quad (89)$$

We can derive $(p_0 + \gamma^t \gamma^1 p_i) \Phi(p) = 0$ from the equation of motion for $\Phi(p)$. The modes propagating along x^1 direction ($p_1 \neq 0, p_2 = 0, p_3 = 0$) obey

$$(p_0 + p_1 \gamma^t \gamma^1) \Phi(p) = \begin{pmatrix} p_0 + p_1 & 0 & 0 & 0 \\ 0 & p_0 - p_1 & 0 & 0 \\ 0 & 0 & p_0 + p_1 & 0 \\ 0 & 0 & 0 & p_0 - p_1 \end{pmatrix} \begin{pmatrix} \Phi_1^+(p) \\ \Phi_2^-(p) \\ \Phi_3^+(p) \\ \Phi_4^-(p) \end{pmatrix} = 0. \quad (90)$$

The equation in (90) describes that (anti-)particles can propagate along only the left or right direction as follow. An anti-particle $\Phi^+(p)$ ($\gamma^t \gamma^1 \Phi^+(p) = \Phi^+(p)$) can not propagate in the right direction parallel to x^1 axis ($x^1 > 0$). On the other hand, the anti-particle $\Phi^-(p)$ ($\gamma^t \gamma^1 \Phi^-(p) = -\Phi^-(p)$) is not able to propagate in the left direction ($x^1 < 0$). Therefore if we define a locally excited state by acting a component of ψ or $\bar{\psi}$ on the ground state, their reduced density matrices depend on the representation of gamma matrices as in (57) and (58). For example, we choose the basis which diagonalizes $\gamma^t \gamma^1$ as in (89) and ψ_1 acts on the ground state. This local operator creates an anti-particle and

it propagates with time. At the late time ($t \gg l$), it is necessarily included in the region A or B. As explained above, it is not able to propagate in the right direction parallel to x^1 axis. Therefore it is included in A (B) with the probability which is bigger than $\frac{1}{2}$ (less than $\frac{1}{2}$). The reduced density matrix in (57) is given by

$$\rho_A = \frac{1}{4} \begin{pmatrix} 3 & 0 \\ 0 & 1 \end{pmatrix}. \quad (91)$$

The result in (91) describes that the antiparticle which created by ψ_1 are included in A (B) with probability $\frac{3}{4}$ ($\frac{1}{4}$)⁴⁵. If we choose a basis in which $(\gamma^t \gamma^1)_{11}$ is given by 0, $\Delta S_A^{(n)}$ is given by $\log 2$.

6 Quasi-Particle Interpretation

In [17, 18, 19], we have interpreted the late time value of $\Delta S_A^{(n)}$ in free massless scalar field theories in terms of entanglement between quasi-particles.

In free fermionic field theory, it is expected that the late time values of $\Delta S_A^{(n)}$ can be interpreted in terms of entanglement between quasi-particles. Therefore we decompose local operators into left moving modes and right moving modes,

$$\begin{aligned} \psi_a &= \psi_a^{L\dagger} + \psi_a^{R\dagger} + \phi_a^L + \phi_a^R, \\ \psi_a^\dagger &= \psi_a^L + \psi_a^R + \phi_a^{L\dagger} + \phi_a^{R\dagger}, \\ \bar{\psi}_a &= \bar{\psi}_a^{L\dagger} + \bar{\psi}_a^{R\dagger} + i(\psi^L \gamma^t)_a + i(\psi^R \gamma^t)_a, \end{aligned} \quad (92)$$

where $\bar{\psi}^{K\dagger}$ is defined by

$$\begin{aligned} \bar{\psi}_a^{L\dagger} &\equiv i(\phi^{L\dagger} \gamma^t)_a, \\ \bar{\psi}_a^{R\dagger} &\equiv i(\phi^{R\dagger} \gamma^t)_a. \end{aligned} \quad (93)$$

The left moving mode and right moving mode of the anti-particle and particle are defined as follows. We decompose ψ, ψ^\dagger into the momentum modes. Their right moving modes (left moving modes) are defined by the sum of the momentum modes whose $\frac{p_0}{p_1}$ is positive ($\frac{p_0}{p_1}$ is negative). As we explained in the previous section, the number of momentum modes which the right moving modes (left moving modes) have depends on the choice of spin's direction. Therefore instead of ordinary anti-commutation relationships ($\{\Phi_a^K, \Phi_b^{K'\dagger}\} = \delta_{KK'} \delta_{ab}$), we impose the following exotic anti-commutation relationship on the particle and anti-particle,

⁴If we act $\psi_1 + \psi_2$ on the ground state, the late time value of $\Delta S_A^{(2)}$ is given by $\log 2$ as we expected

⁵ If you choose the bases which diagonalize $\gamma^t \gamma^1$ in 2d massless free fermionic field theory, a component of ψ ($\bar{\psi}$) is able to propagate in the only left or right direction parallel to x^1 . Therefore $\Delta S_A^{(n)}$ vanish for the locally excited states generated by acting a component of ψ ($\bar{\psi}$) on the ground state.

$$\begin{aligned}
\{\phi_a^R, \phi_b^{R\dagger}\} &= \left(\delta_{ab} - \frac{1}{2} (\gamma^t \gamma^1)_{ab} \right), \\
\{\phi_a^L, \phi_b^{L\dagger}\} &= \left(\delta_{ab} + \frac{1}{2} (\gamma^t \gamma^1)_{ab} \right), \\
\{\psi_a^{R\dagger}, \psi_b^R\} &= \left(\delta_{ab} - \frac{1}{2} (\gamma^t \gamma^1)_{ab} \right), \\
\{\psi_a^{L\dagger}, \psi_b^L\} &= \left(\delta_{ab} + \frac{1}{2} (\gamma^t \gamma^1)_{ab} \right), \\
\{\bar{\psi}_a^R, \bar{\psi}_b^{R\dagger}\} &= \left(\delta_{ab} - \frac{1}{2} (\gamma^1 \gamma^t)_{ab} \right), \\
\{\bar{\psi}_a^L, \bar{\psi}_b^{L\dagger}\} &= \left(\delta_{ab} + \frac{1}{2} (\gamma^1 \gamma^t)_{ab} \right).
\end{aligned} \tag{94}$$

The vacuum $|0\rangle = |0\rangle_L \otimes |0\rangle_R$ is defined by

$$\phi_a^K |0\rangle = \psi_a^K |0\rangle = \bar{\psi}_a^K |0\rangle = 0, \tag{95}$$

where $K = L, R$. The number of momentum modes which the left and right moving modes have depends on the choice of $\gamma^t \gamma^1$ (the choice of the spin's direction). Therefore, it is reasonable that the anti-commutation for them is given by that in (94)⁶. We claim that the exotic anti-commutation relationship in (94) can be applied to $\Delta S_A^{(n)}$ in 4 dimensional free massless fermionic field theory. However in $d(\neq 4)$ dimensional spacetime, that in (94) should be deformed. For example, in 2 dimensional spacetime the reduced density matrix for the state excited by a local operator constructed of chiral and anti-chiral operators should become

$$\rho_A = \frac{1}{2} \begin{pmatrix} 1 + (\gamma^t \gamma^1)_{aa} & 0 \\ 0 & 1 - (\gamma^t \gamma^1)_{aa} \end{pmatrix}. \tag{96}$$

Therefore the anti-commutation relation in (94) should change to another one.

This way, we can construct reduced density matrices which agree with those which are obtained by the replica trick as we will see later. In following subsections we will compute them under this decomposition in various examples in 4 dimensional free massless fermionic field theory.

6.1 Various Examples

Here we compute reduced density matrices for various locally excited states under the quasi-particle interpretation.

⁶However we find this exotic anti-commutation relationship heuristically.

6.1.1 ρ_A for ψ_a

A locally excited states is given by

$$|\Psi\rangle = \mathcal{N} \psi_a |0\rangle, \quad (97)$$

which is variant under the $SL(2, \mathbf{C})$ transformation. Under the decomposition in (92), this state is given by

$$|\Psi\rangle = \frac{1}{\sqrt{2}} [\psi_a^{L\dagger} |0\rangle_L \otimes |0\rangle_R + |0\rangle_L \otimes \psi_a^{R\dagger} |0\rangle_R], \quad (98)$$

after the normalization constant \mathcal{N} is determined.

Normalized orthogonal left and right moving states are given by

$$\begin{aligned} &|0\rangle_L, \\ &|0\rangle_R, \\ &|\psi_a^L\rangle_L = \mathcal{N}^L \psi_a^{L\dagger} |0\rangle_L, \\ &|\psi_a^R\rangle_R = \mathcal{N}^R \psi_a^{R\dagger} |0\rangle_R, \end{aligned} \quad (99)$$

where $(\mathcal{N}^L)^2$ and $(\mathcal{N}^R)^2$ are given by

$$\begin{aligned} (\mathcal{N}^L)^2 &= \frac{1}{1 + \frac{(\gamma^t \gamma^1)_{aa}}{2}}, \\ (\mathcal{N}^R)^2 &= \frac{1}{1 - \frac{(\gamma^t \gamma^1)_{aa}}{2}}. \end{aligned} \quad (100)$$

A reduced density matrix ρ_A is defined by $\text{tr}_L \rho$. It is given by

$$\rho_A = \frac{1}{4} [(2 + (\gamma^t \gamma^1)_{aa}) |0\rangle_R \langle 0|_R + (2 - (\gamma^t \gamma^1)_{aa}) |\psi_a^R\rangle_R \langle \psi_a^R|_R] \quad (101)$$

which agrees with the one obtained by the replica trick. When $(\gamma^t \gamma^1)_{aa}$ vanishes, $\Delta S_A^{(n)}$ are given by $\log 2$. In the $n \rightarrow 1$ limit, it is given by entanglement entropy for maximally entangled state (EPR state). If we choose gamma matrices as in (89), the anti-particles created by ψ_1 is not able to propagate in the right direction parallel to x^1 axis. Therefore the probability with which it is finally included in B is larger than the one with which it is included in A at the late time. The reduced density matrix in (101) agrees with our intuitive expectation.

6.1.2 ρ_A for $\bar{\psi}\psi$

A locally excited states is given by

$$|\Psi\rangle = \mathcal{N} \bar{\psi} \psi |0\rangle, \quad (102)$$

which is invariant under the $SL(2, \mathbf{C})$ transformation.

By using an unitary transformation, $\gamma^t \gamma^1$ can be diagonalized. After diagonalize it, the reduced density matrix for this state can be computed easily. Here it is given by that in (89)

Under the decomposition in (92), the state in (102) is given by

$$|\Psi\rangle = \frac{1}{4} \sum_a [\bar{\psi}_a^{L\dagger} \psi_a^{L\dagger} + \bar{\psi}_a^{L\dagger} \psi_a^{R\dagger} + \bar{\psi}_a^{R\dagger} \psi_a^{L\dagger} + \bar{\psi}_a^{R\dagger} \psi_a^{R\dagger}] |0\rangle_L \otimes |0\rangle_R, \quad (103)$$

after the normalization constant \mathcal{N} is determined.

Normalized orthogonal states are given by

$$\begin{aligned} &|0\rangle_L, \\ &|0\rangle_R, \\ &|\bar{\psi}^L \psi^L\rangle_L = \mathcal{N}^{LL} \sum_a \bar{\psi}_a^{L\dagger} \psi_a^{L\dagger} |0\rangle_L, \\ &|\bar{\psi}^R \psi^R\rangle_R = \mathcal{N}^{RR} \sum_a \bar{\psi}_a^{R\dagger} \psi_a^{R\dagger} |0\rangle_R, \\ &|\psi_a^L\rangle = \tilde{\mathcal{N}}_a^L \psi_a^{L\dagger} |0\rangle_L, \\ &|\psi_a^R\rangle = \tilde{\mathcal{N}}_a^R \psi_a^{R\dagger} |0\rangle_R, \\ &|\bar{\psi}_a^L\rangle = \bar{\mathcal{N}}_a^L \psi_a^{L\dagger} |0\rangle_L, \\ &|\bar{\psi}_a^R\rangle = \bar{\mathcal{N}}_a^R \psi_a^{R\dagger} |0\rangle_R, \end{aligned} \quad (104)$$

where normalization factors are given by

$$\begin{aligned} (\mathcal{N}^{LL})^2 &= (\mathcal{N}^{RR})^2 = \frac{1}{3}, \\ (\tilde{\mathcal{N}}_1^R)^2 &= (\tilde{\mathcal{N}}_3^R)^2 = (\tilde{\mathcal{N}}_2^L)^2 = (\tilde{\mathcal{N}}_4^L)^2 = (\bar{\mathcal{N}}_2^R)^2 = (\bar{\mathcal{N}}_4^R)^2 = (\bar{\mathcal{N}}_1^L)^2 = (\bar{\mathcal{N}}_3^L)^2 = 2, \\ (\tilde{\mathcal{N}}_2^R)^2 &= (\tilde{\mathcal{N}}_4^R)^2 = (\tilde{\mathcal{N}}_1^L)^2 = (\tilde{\mathcal{N}}_3^L)^2 = (\bar{\mathcal{N}}_1^R)^2 = (\bar{\mathcal{N}}_3^R)^2 = (\bar{\mathcal{N}}_2^L)^2 = (\bar{\mathcal{N}}_4^L)^2 = \frac{2}{3}. \end{aligned} \quad (105)$$

A reduce density matrix is given by

$$\begin{aligned} \rho_A &= \text{tr}_L \rho = \\ &= \frac{12}{64} |0\rangle_R \langle 0|_R + \sum_i \frac{\mathcal{M}_i}{64} |\psi_i^R\rangle_R \langle \psi_i^R|_R + \sum_i \frac{\bar{\mathcal{M}}_i}{64} |\bar{\psi}_i^R\rangle_R \langle \bar{\psi}_i^R|_R + \frac{12}{64} |\bar{\psi}^R \psi^R\rangle_R \langle \bar{\psi}^R \psi^R|_R, \end{aligned} \quad (106)$$

where \mathcal{M}_i and $\bar{\mathcal{M}}_i$ are given by

$$\begin{aligned} \mathcal{M}_1 &= \mathcal{M}_3 = \bar{\mathcal{M}}_2 = \bar{\mathcal{M}}_4 = 1, \\ \mathcal{M}_2 &= \mathcal{M}_4 = \bar{\mathcal{M}}_1 = \bar{\mathcal{M}}_3 = 9. \end{aligned} \quad (107)$$

This reduced density matrix agrees with the one obtained by the replica trick.

6.1.3 ρ_A for $\psi^\dagger\psi$

A locally excited states is given by

$$|\Psi\rangle = \mathcal{N}\psi^\dagger\psi|0\rangle, \quad (108)$$

which is variant under the $SL(2, \mathbf{C})$ transformation. However $\Delta S_A^{(n)}$ for (108) is invariant in the replica trick. Therefore we diagonalize $\gamma^t\gamma^1$ as in (89). After diagonalizing it, ρ_A is given by

$$\rho_A = \text{tr}_R \rho = \frac{20}{64} |\phi^R\psi^R\rangle_R \langle\phi^R\psi^R|_R + \frac{20}{64} |0\rangle_R \langle 0|_R + \frac{3}{64} \sum_i |\phi_i^R\rangle_R \langle\phi_i^R|_R + \frac{3}{64} \sum_i |\psi_i^R\rangle_R \langle\psi_i^R|_R. \quad (109)$$

7 Conclusions and Discussions

In this paper we have studied the dynamics of quantum entanglement. We considered the 4 dimensional free massless fermionic field theory. Locally excited states are generated by being acted on the ground state by various local operators. We defined the excesses of (Rényi) entanglement entropies $\Delta S_A^{(n)}$ by subtracting (Rényi) entanglement entropies for the ground state from those for locally excited states. $\Delta S_A^{(n)}$ are finite quantities. We found that $\Delta S_A^{(n)}$ vanish if $t \leq l$. If $t > l$, $\Delta S_A^{(n)}$ increase and finally approach constants as in scalar field theory [17, 18, 19].

We found that if the locally excited state is given by $\mathcal{N}\psi_a|0\rangle, \mathcal{N}\bar{\psi}_a|0\rangle$, components of its reduced density matrices include $\gamma^t\gamma^1$. Therefore they depend on the direction of spin. A component of ψ or $\bar{\psi}$ creates an anti-particle or particle. Their propagation depends on the direction of spin. Therefore components of reduced density matrices for those locally excited states depend on the direction of spin. We also generated locally excited states $\mathcal{N}\psi^\dagger\psi|0\rangle$ and $\mathcal{N}\bar{\psi}\psi|0\rangle$ and investigated the time evolution of $\Delta S_A^{(n)}$ for them. We found that $\Delta S_A^{(n)}$ are invariant under the lorentz transformation although $\mathcal{N}\psi^\dagger\psi|0\rangle$ is not invariant under the lorentz transformation.

We found that the time evolution and the late time values of $\Delta S_A^{(n)}$ can be interpreted in terms of quasi-particles. However in the fermionic field theory, the number of modes which propagate in the left ($x^1 < 0$) or the right ($x^1 > 0$) direction depend on the choice of the spin's direction. Therefore we need to impose exotic anti-commutation relation in (94) on quasi-particles. In the 4 dimensional free massless fermionic field theory, the results by the replica trick can be interpreted as the quantum entanglement between quasi-particles if the relationship in (94) is applied to them. In the $d(\neq 4)$ dimensional free fermionic field theory, anti-commutation relationship should be changed.

We would like to list a few of future problems:

- It is interesting to study charged (Rényi) entanglement entropies for locally excited states and holographic field theory.

- It is important to study how we should deform the relationship in (94) in $d(\neq 4)$ dimensional free massless fermionic field theory.
- It is interesting to study the time evolution of $\Delta S_A^{(n)}$ in non-relativistic field theory.
- It would be expected that gamma matrices included in reduced density matrices is related to the modular Hamiltonian. It is interesting to clarify the relationship between the spin dependence of the reduced matrices and the entanglement Hamiltonian.

Acknowledgement

MN thanks Tadashi Takayanagi and Masaharu Tanahashi for useful discussions and advices. We thank Mitsutoshi Fujita for collaboration in the early stage of this work. We also thank Tatsuma Nishioka, Daniel Grumiller, Max Riegler and Pawel Caputa for useful discussions.
